

Magic Wear Rate

Measuring methods

Time series

Forecast models

Procedure

Quantitative description of the **wear behavior** of the tram and subway net.

Dependent on:

- ❖ Route layout (curvature)
- ❖ Inspection (vehicle dynamics and load)
- ❖ Rail system (nonballasted track, sleeper track)
- ❖ Steel grade (temper of steel)

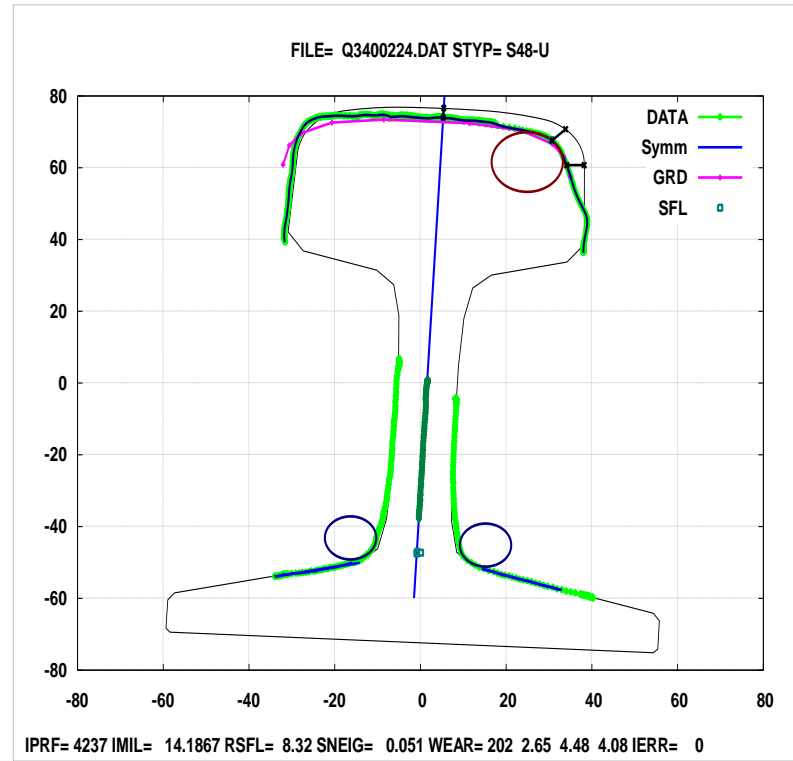

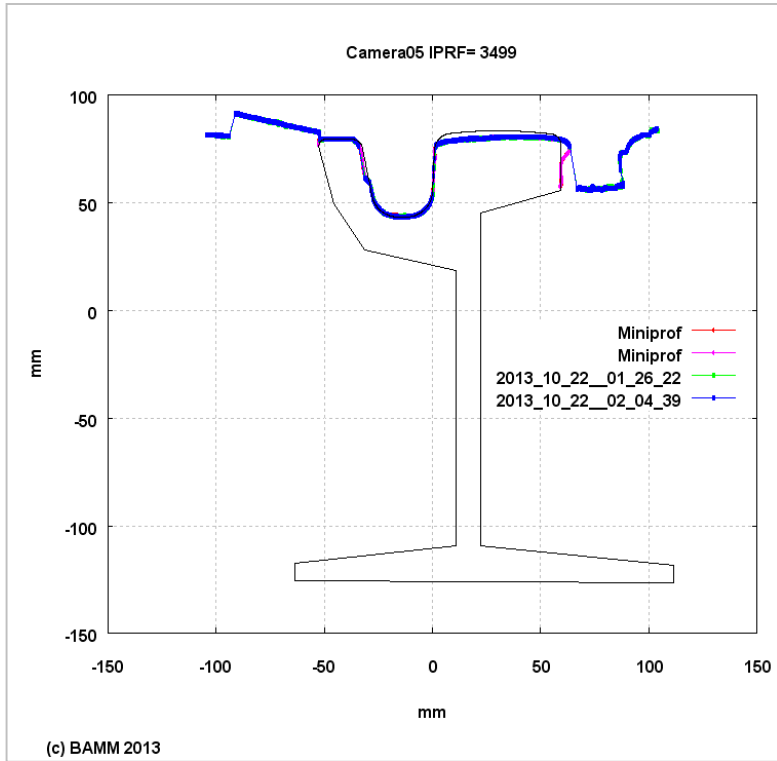

Aim is generation of time series and curvature dependent **wear rates formulae** by using the data of both track measuring cars

Track geometry car (Tram)

Laser based profile (wear) measurement

Modus operandi

Calculation of wear rates of the subway:

Analysis of measurement runs from 2006 to 2016

Rail **wear horizontal, lateral** and **45°** (combined)

Classification of routes into **discrete sections**

Approximation in the **time domain**

Categorization into 10 **curvature classes**

Filtering by track types

Statistical summarization (by subway lines)

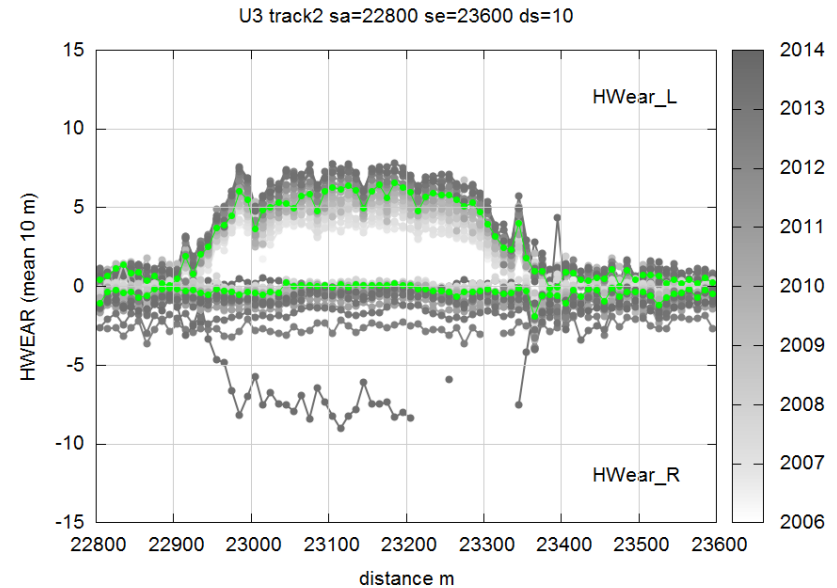

Raw data

Single test run and time series of the horizontal wear

Conclusion

A quantitative description of the wear behavior of rails of the tram and subway net can be given in dependence of

- ❖ Line routing (curvature)
- ❖ Inspection (vehicle dynamics and load)
- ❖ Rail system (nonballasted track, sleeper track)

by an analytical formula („Magic Wear Rate“).

For single subway lines significant differences occur in the wear behavior. The horizontal wear turned out to be an essential influence parameter. Different types of the track system play a minor role.

Conclusion

For the tram the dominating dependence on the curvature is clearly visible as well; the influence of the inspection is essential. Obviously the arc lengths are shorter and the differences in the amount of available data larger. This leads to higher ranges.
